# Root RAID HOWTO cookbook

Michael A. Robinton, [michael@bzs.org](mailto:michael@bzs.org)

v1.13, July 17, 2000

---

*This document only applies to the **OLD** raidtools, versions 0.50 and under. The workarounds and solutions addressed in this write up have largely been made obsolete by the vast improvement in the 0.90 raidtools and accompanying kernel patch to the 2.0.37, 2.2x and 2.3x series kernels. You may find the detailed descriptions useful, particularly if you plan to run root raid or use initrd. Check these links for a reference to set up of Boot Root Raid using conventional LILO and accompanying initrd working scripts. What follows is the description of the now **OBSOLETE Root RAID HOWTO**. This document was originally written to provide a cookbook for creating a root mounted raid filesystem and companion fallback rescue system using linux initrd. There are complete step-by-step instruction for both raid1 and raid5 md0 devices. Each step is accompanied by an explanation of it's purpose. Included with this revision is a generic **linuxrc** initrd file which may be configured with a single three line /etc/raidboot.conf file for raid1 and raid5 configurations.*

---

## 1. Introduction

The reader is assumed to be familiar with the various types of raid implementations, their advantages and drawbacks. This is not a tutorial, just a set of instructions on how to implement root mounted raid on a linux system. All of the information necessary to become familiar with linux raid is listed here directly or by reference, please read it before send e-mail questions.

### 1.1 Where to get Up-to-date copies of this document.

Click here to browse the [author's latest version](#) of this document. Corrections and suggestions welcome!

Root-RAID-HOWTO -- OBSOLETE

Available in LaTeX (for DVI and PostScript), plain text, and HTML.

<http://www.linuxdoc.org/HOWTO/Root-RAID-HOWTO.html>

Available in SGML and HTML.

<ftp.bizsystems.net/pub/raid/>

### 1.2 More up-to-date Boot Root Raid with LILO howto

Available in LaTeX (for DVI and PostScript), plain text, and HTML.

<http://www.linuxdoc.org/HOWTO/Boot+Root+Raid+LILO.html>

Available in SGML and HTML.

<ftp.bizsystems.net/pub/raid/>

## 1.3 Bugs

As of this writing, the problem of stopping a root mounted RAID device has not yet been solved in a satisfactory way. A work-around proposed by Ed Welbon and implemented by Bohumil Chalupa is incorporated into this document which eliminates the need for a long ckraid at each boot for raid1 and raid5 devices. Without the workaround, it is necessary to **ckraid** the **md** device each time the system is re-booted. On a large array this can cause a severe availability performance degradation. On my 6 gig RAID1 device running on a Pentium 166 with 128 megs of ram, it takes well over half an hour to ckraid :-( after each re-boot. It takes over an hour on my 13 gig RAID5 array with a 20mb/sec scsi adaptor.

The workaround stores the status of the array at shutdown on the **real** boot device and compares it to a reference status placed there when the system is first built. If the status's match at reboot, the superblock on the array is rebuilt on the next boot, otherwise the operator is notified of the status error and the rescue system is left running with all the raid tools available.

Rebuilding the superblock causes the system to ignore that the array was powered down without mdstop by marking all the drives as **OK**, as if nothing happened. This only works if all the drives are OK at shutdown. If the array was operating with a bad drive, the operator must remove the bad drive prior to restarting the md device or the data can be corrupted.

None of this applies to raid0 which does not have to be mdstopped before shutdown.

Final proposed solutions to this problem include a **finalrd** similar to **initrd**, and **mdrootstop** which writes the **clean** flags to the array during shutdown when it is mounted read only. I am sure there are others.

In the mean time, the problem has been by-passed for now Please let me know when this problem is solved more cleanly!!!

## 1.4 Acknowledgements

The writings and e-mail from the following individuals helped to make this document possible. Many of the ideas were *stolen* from the helpful work of others, I have just tried to put it all in **COOKBOOK** form so that it is straightforward to use. My thanks to:

- Linas Vepstas for the RAID howto that explained most of this to me.
- Gadi Oxman for answering my dumb 'newbie' questions.
- Ed Welbon for the excellent **initrd.md** package that inspired me to write this.
- Bohumil Chalupa for implementing the re-boot 'workaround' that allows **root-mounted-raid** to work in a production environment.
- Keith W. for his explanation of setting up root raid with **RedHat**.
- and many others who contributed to this work in one way or another.

## 2. What you need BEFORE YOU START

The packages you need and the documentation that answers the most common questions about setting up and running raid are listed below. Please review them thoroughly.

### 2.1 Required Packages

You need to obtain the most recent versions of these packages.

- a linux kernel that supports raid, initrd and /dev/loopx

I used [linux-2.0.33](#) from sunsite

- [raid145-971022-2.0.31](#) patch adds support for raid1/4/5
- [raidtools-pre3-0.42](#) tools to create and maintain raid devices (documentation too).
- [Gadi's raid stop patch](#) in Appendix E.
- [linuxthreads-0.71](#) required threads package. Use ftp, browser doesn't work  
<ftp.inria.fr/INRIA/Projects/cristal/Xavier.Leroy>
- A Linux distribution, ready to install.

I used [Slackware-3.4](#)

Helpful but not required

- [raidboot-0.01.tar.gz](#) pre-built raid rescue/boot system.

The detailed instructions in this document are based on the above packages. If the packages have been updated or you use a different linux distribution, you may have to modify the procedures you find here.

The patches, tool assortment, etc... may vary with 2.1 kernels. Please check the most recent documentation at:

<ftp.kernel.org/pub/linux/daemons/raid/>

### 2.2 Other similar implementations.

I chose to include in the kernel all of the pieces necessary to run from boot without loading any modules. My kernel image is a little over 300k compressed.

Take a look at [Ed Welbon's initrd.md.tar.gz](#) for another way to make a bootable raid device. He uses loadable modules. A look at his concise scripts will show you how it is done if you need a very small kernel with modules.

<http://www.realtime.net/~welbon/initrd.md.tar.gz>

## 2.3 Documentation -- Recommended Reading

Please read:

`/usr/src/linux/Documentation/initrd.txt`

as well as the documentation and man pages that accompany the raidtools set. In particular, read **man mdadd** as well as the **QuickStart.RAID** document included in the raidtools package.

You may also wish to review:

- [BootPrompt-HOWTO](#)
- **man lilo**
- **man lilo.conf**

## 2.4 RAID resources

- [www.linas.org/linux/Software-RAID/Software-RAID.html](http://www.linas.org/linux/Software-RAID/Software-RAID.html)
- [www.ssc.com/lg/issue17/raid.html](http://www.ssc.com/lg/issue17/raid.html)
- [linas.org/linux/raid.html](http://linas.org/linux/raid.html)
- <ftp.kernel.org/pub/linux/daemons/raid/>
- [www.realtime.net/~welbon/initrd.md.tar.gz](http://www.realtime.net/~welbon/initrd.md.tar.gz)
- [luthien.nuclecu.unam.mx/~miguel/raid/](mailto:luthien.nuclecu.unam.mx/~miguel/raid/)

Mailing lists can be joined at:

- [majordomo@nuclecu.unam.mx](mailto:majordomo@nuclecu.unam.mx) *send a message to subscribe raiddev*

send mail to: [raiddev@nuclecu.unam.mx](mailto:raiddev@nuclecu.unam.mx)

- [majordomo@vger.rutgers.edu](mailto:majordomo@vger.rutgers.edu) *send a message to subscribe linux-raid*

send mail to: [linux-raid@vger.rutgers.edu](mailto:linux-raid@vger.rutgers.edu) *(this seems to be the most active list)*

## 3. Quick Start for ROOT RAID

If you use **RedHat**, see the [Howto set up RedHat](#) section in Appendix H. I have not tried this. If you use it successfully, please let me know so I can update this document.

If you don't want to try and build and debug the rescue system, you can get a generic one created from Slackware-3.4 from:

<ftp.bizsystems.com/pub/raid/raidboot-0.01.tar.gz>

Perform the following steps:

- Compile the raid enabled kernel with built in support for your disk subsystem
- Test that the raid array will configure and mount correctly

## Root RAID HOWTO cookbook

- Build your OS on the raid system
- Correct the entries in **fstab** to show **/dev/md0** as the root device. Make sure that the partition(s) you use for booting are included in **fstab**.
- Modify your shutdown halt and reboot script(s) (mine is /etc/rc.d/rc.6) as shown in Modifying the rc-scripts for SHUTDOWN
- Copy the following from you development filesystem to the rescue system AND the new raid system

```
cd /root/raidboot
mkdir mnt
gzip -d rescue.clean
losetup /dev/loop0 rescue.clean
mount /dev/loop0 mnt
```

copy these files

```
cp -p /etc/* mnt/etc
cp -p /etc/rc.d/* mnt/etc/rc.d
    {or as appropriate for your system}
cp -a /lib/modules/* mnt/lib/modules
```

Some Linux distributions include a test for the **ro/rw** status of the root file system. The **rc startup** files need to have this test removed for the initrd rescue system. See the instructions in the section on Correctons for Rescue System.

Correct the entries in **fstab** to show **/dev/md0** as the root device. Make sure that the partition(s) you use for booting is included in **fstab**.

Create **/etc/raidboot.conf** which describes the raid boot configuration. This file may **NOT** contain comments in the first three lines, after that it doesn't matter.

raidboot.conf

```
/dev/sda1 /dev/sda2
raidboot
raid5.conf
# comments may only be placed 'after' the three
# configuration lines.
#
# This is '/etc/raidboot.conf'
#
# line one, the partition(s) containing the 'initrd' raid-rescue system
#     It is not necessary to boot from these partitions, however,
#     since the rescue system will not fit on floppy, it is necessary
#     to know which partitions are to be used to load the rescue system
#
# line two, the path to the raidboot config information
#     Where the shutdown status, etc... is located at boot time
#     It does NOT include the mount point information, only 'path'
#     /mntpoint/'path'
#
# line -3-, name of the raid configuration file
#     Current raid configuration file i.e. raid1.conf, raid5.conf
```

A few more things to do and the raid systems is ready to boot.

Create rc.raidown, as described in Appendix F, and copy it to /etc/rc.d on the rescue, development, and raid system. Unmount the rescue system and zip it.

```
umount mnt
losetup -d /dev/loop0
mv rescue.clean rescue
gzip rescue
```

Copy the rescue file to the raidboot partitions.

```
cp rescue.gz /mnt_point(1)/raidboot
cp rescue.gz /mnt_point(2)/raidboot
```

Activate the raid array.

```
mdadd -ar
```

Save the **good** reference status to the raidboot partition

```
cat /proc/mdstat | grep md0 > /mnt_point(1)/raidboot/raidgood.ref
cat /proc/mdstat | grep md0 > /mnt_point(1)/raidboot/raidgood.ref
```

Lastly, configure the boot program as outlined in [Boot Time Configuration Parameters](#) and reboot your system onto the raid array.

## 4. *initrd* Cookbook for root mounted RAID

This is the procedure to make an 'initrd' ramdisk with rescue tools for raid.

Specifically, this document refers to RAID1 and RAID5 implementations.

### 4.1 Security Reminder

The rescue file system may be used stand alone. Should your raid array fail to mount, you are left with the rescue system mounted and running. TAKE THE APPROPRIATE SECURITY PRECAUTIONS!!!

### 4.2 Build the Kernel and Raid Tools

The first thing that must be done is to patch and build your kernel and become familiar with the raid tools. Make sure and include [Gadi's raid stop patch](#) in Appendix E. Configure, mount and test your raid device(s). The details of how to do this are included in the **raidtools** package and briefly reviewed later in this document.

### 4.3 Build the *initrd* Rescue and Boot filesystem

I used the **Slackware-3.4** distribution to build both the Rescue/Boot filesystem and the filesystem for the production machine. Any linux distribution should work fine. If you use a different distribution, review the Slackware specific portion of this procedure and modify it to suit your needs.

I use loadlin to boot the kernel image and ramdisk from a dos partition simply because there are oddball devices in my system that have dos configuration software. Lilo will work just as well and a small linux partition can be used instead containing only the raid/boot files and the **lilo** record.

## Root RAID HOWTO cookbook

For the raid boot/rescue system, I chose to create a minimum ramdisk system using the Slackware 'setup' script followed by installing the 'linuxthreads' package and 'raidtools' over the clean Slackware installation on my ramdisk. I used the *identical* procedure to build the production system. So the rescue and production systems are very similar.

This installation process gives me a 'bare' system (save a copy of the file) to which I overlay

```
/lib/modules/2.x.x.....  
/etc .... with a modified fstab, mdtab, raidX.conf, raidboot.conf  
/etc/rc.d  
/dev/md*
```

from my current system to customize it for the particular kernel and machine that it is/will-be running on.

This makes the boot/rescue system the same system that is running on the root mounted raid device, just skinnyed down a bit, while allowing the library, etc... revisions to always be current.

## 4.4 Start the STEP by STEP instructions

From the root home directory (/root):

```
cd /root  
mkdir raidboot  
cd raidboot
```

Create a mountpoints to work on

```
mkdir mnt  
mkdir mnt2
```

Make a file large enough to do the file system install. This will be a lot larger than the final rescue file system. I chose 24 megs since 16 megs is not large enough

```
dd if=/dev/zero of=build bs=1024k count=24
```

associate the file with a loop device and generate an ext2 file system on the file

```
losetup /dev/loop0 build  
mke2fs -v -m0 -L initrd /dev/loop0  
mount /dev/loop0 mnt
```

## 4.5 Install the distribution - Slackware Specific

...skip Slackware Specific stuff and go to next section.

Now that an empty filesystem is created and mounted, run "setup".

```
Specify          /root/raidboot/mnt
```

as the '**target**'. The source is whatever you normally install from. Select the packages you wish to install and proceed but **DO NOT** configure.

## Root RAID HOWTO cookbook

Choose 'EXPERT' prompting mode.

I chose 'A', 'AP', and 'N' installing only the minimum to run the system plus an editor I am familiar with (vi, jed, joe) that is reasonably compact.

```

x mqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqqj x
```

From the 'N' package I only loaded TCPIP. This isn't really necessary, but is very handy and allows access to the network while working on a repair or update with the root raid array dismounted. TCPIP also contains 'biff' which is used by some of the applications in 'A'. If you don't install 'N' you might want to install the biff package anyway.

```

With the installation complete, say no to everything else (no to all configuration requests) and exit the script.

## 4.6 Install linux pthreads

Now you must install the 'linuxthreads-0.71' library. I have included this diff for the linuxthreads Makefile rather than explain the details of the installation by hand. Save the original Makefile, apply the diff and then:

```
cd /usr/src/linuxthreads-0.71
```

## Root RAID HOWTO cookbook

```
patch
    make
    make install

-----diff Makefile.old  Makefile.raid-----
2a3,13
> # If you are building "linuxthreads" for installation on a mount
> # point which is not the "root" partition, redefine 'BUILDIR' to
> # the mount point to use as the "root" directory
> # You may wish to do this if you are building an 'initial ram disk'
> # such as used with bootable root raid devices.
> # REQUIRES ldconfig version 1.9.5 or better
> # do ldconfig -v to check
> #
> BUILDIR=/root/raidboot/mnt
> #BUILDIR=
>
81,82c92,93
<     install pthread.h $(INCLUDEDIR)/pthread.h
<     install semaphore.h $(INCLUDEDIR)/semaphore.h
---
>     install pthread.h $(BUILDIR)$(INCLUDEDIR)/pthread.h
>     install semaphore.h $(BUILDIR)$(INCLUDEDIR)/semaphore.h
84c95
<     test -f /usr/include/sched.h || install sched.h $(INCLUDEDIR)/sched.h
---
>     test -f $(BUILDIR)/usr/include/sched.h || install sched.h $(BUILDIR)$(INCLUDEDIR)/

>     rm -f $(BUILDIR)$(LIBDIR)/$(SHLIB0)
>     ln -s $(SHAREDLIBDIR)/$(SHLIB) $(BUILDIR)$(LIBDIR)/$(SHLIB0)
> ifneq ($(BUILDIR),)
>     ldconfig -r ${BUILDIR} -n $(SHAREDLIBDIR)
> else
91c105,106
<     cd man; $(MAKE) MANDIR=$(MANDIR) install
---
> endif
>     cd man; $(MAKE) MANDIR=$(BUILDIR)$(MANDIR) install
```

## 4.7 Install Raid Tools

The next step is the installation of the raid tools. raidtools-0.42

You must run the "configure" script to point the Makefile at the build directory for the ramdisk files

```
cd /usr/src/raidtools-0.42
configure --sbindir=/root/raidboot/mnt/sbin --prefix=/root/raidboot/mnt/usr
make
make install
```

Now!! the Makefile for install is not quite right so do the following to clean up. This will be fixed in future releases so that the re-linking will not be necessary.

Fix the make install error

The file links specified in the Makefile at 'LINKS' must be removed and re-linked to operate properly.

```
cd /root/raidboot/mnt/sbin
ln -fs mdadd mdrun
ln -fs mdadd mdstop
```

## 4.8 Remove un-needed directories and files from new filesystem.

Delete the following directories from filesystem (CAUTION DON'T DELETE FROM YOUR RUNNING SYSTEM) it's easy to do, guess how I found out!!!

```
cd /root/raidboot/mnt
rm -r home/ftp/*
rm -r lost+found
rm -r usr/doc
rm -r usr/info
rm -r usr/local/man
rm -r usr/man
rm -r usr/openwin
rm -r usr/share/locale
rm -r usr/X*
rm -r var/man
rm -r var/log/packages
rm -r var/log/setup
rm -r var/log/disk_contents
```

## 4.9 Create /dev/mdx

The last step simply copies the /dev/md\* devices from the current file system onto the rescue file system. You could create these with mknod.

```
cp -a /dev/md* /root/raidboot/mnt/dev
```

## 4.10 Create a bare filesystem suitable for *initrd*

Now you have a clean re-useable filesystem ready for customization. Once customized, this file system can be used for rescue should the raid device(s) become corrupted and the raid tools needed to fix them. It will also be used to boot and root-mount the raid device by adding the linuxrc file which will be discussed next.

Copy the file system to a smaller device for the initrd file, 16 megs should be large enough.

Create the smaller file system and mount it

```
cd /root/raidboot
dd if=/dev/zero of=bare.fs bs=1024k count=16
```

## Root RAID HOWTO cookbook

associate the file with a loop device and generate a ext2 file system on the file

```
losetup /dev/loop1 bare.fs
mke2fs -v -m0 -L initrd /dev/loop1
mount /dev/loop1 mnt2
```

Copy the 'build' file system to 'bare.fs'

```
cp -a mnt/* mnt2
```

Save the 'bare.fs' system before customization so later update is easy. The 'build' file system is no longer needed and may be deleted.

```
cd /root/raidboot
umount mnt
umount mnt2
losetup -d /dev/loop0
losetup -d /dev/loop1
rm build
cp bare.fs rescue
gzip -9 bare.fs
```

## Create the BOOT/RESCUE *initrd* filesystem

Now copy the system dependent items that match the kernel from the development platform, or you can manually modify the files in the rescue file system to match your target system.

```
losetup /dev/loop0 rescue
mount /dev/loop0 mnt
```

Make sure your etc directory is clean of \*~, core and log files. The next 2 commands creates some warning messages, ignore them.

```
cp -dp /etc/* mnt/etc
cp -dp /etc/rc.d/* mnt/etc/rc.d

mkdir mnt/lib/modules
cp -a /lib/modules/2.x.x mnt/lib/modules <--- your current 2.x.x
```

## Corrections for the Rescue System

Edit the following files to correct them for your rescue system. Some file names listed below are Slackware specific but have equivalents in other distributions.

```
cd mnt

Non-network
  etc/fstab
  etc/mdtab          should work OK

Network
  etc/hosts
  etc/resolv.conf
  etc/hosts.equiv    and related files
  etc/rc.d/rc.inet1  correct ip#, mask, gateway, etc...
  etc/rc.d/rc.S      remove entire section on file system status
                    from:
```

## Root RAID HOWTO cookbook

```
# Test to see if the root partition is read-only
to but not including:
# remove /etc/mtab* so that mount will .....
This avoids the annoying warning that
the ramdisk is mounted rw.
etc/rc.d/rc.xxxxx      others as required, see later on in this doc
root/.rhosts           if present
home/xxxx/xxxx         others as required

WARNING:      The above procedure moves your password and shadow
              files onto the rescue disk!!!!

WARNING:      You may not wish to do this for security reasons.
```

Create any directories for mounting /dev/disk... as may be required that are unique to your system. These are the mountpoints for booting the system (boot partition and backup boot partition). My system boot from dos using **loadlin**, however linux partition(s) and lilo will work fine. My system uses:

```
cd /root/raidboot/mnt      <--- initrd root
mkdir dosa                 dos partition mount point
mkdir dosb                 dos mirror mount point
```

The rescue file system is complete!

You will note upon examination of the files in the rescue file system, that there are still many files that could be deleted. I have not done this since it would overly complicate this procedure and most raid systems have adequate disk and memory. If you wish to skinny down the file system, go to it!

## 4.11 Making 'initrd' boot the RAID device - linuxrc

To make the rescue disk boot the raid device, you need only copy the executable script file:

### **linuxrc**

to the root of the device.

The theory of operation for this **linuxrc** file is discussed in [Appendix G, linuxrc theory of operation](#).

A very simple and much easier to understand (working) linuxrc is included in [Appendix D, obsolete linuxrc and shutdown scripts](#). Copy the following text to **linuxrc** and save in your development area.

```
----- linuxrc -----
#!/bin/sh
# ver 1.13 3-6-98
#
##### BEGIN 'linuxrc' #####
#               DEFINE FUNCTIONS               #
#####
# Define 'Fault' function in the event something
# goes wrong during the execution of 'linuxrc'
#
FaultExit () {
# correct fstab to show '/dev/ram0' for rescue system
/bin/cat /etc/fstab | {
while read Line
```

## Root RAID HOWTO cookbook

```
do
    if [ -z "$( echo ${Line} | /usr/bin/grep md0 )" ]; then
        echo ${Line}
    else
        echo "/dev/ram0 / ext2 defaults 1 1"
    fi
done
} > /etc/tmp.$$
/bin/mv /etc/tmp.$$ /etc/fstab
# point root at /dev/ram0 (the rescue system)
echo 0x100>/proc/sys/kernel/real-root-dev
/bin/umount /proc
exit
}

# Define 'Warning' procedure to print banner on boot terminal
#
Warning () {
    echo '*****'
    echo -e " $*"
    echo '*****'
}

# Define 'SplitKernelArg' to help extract 'Raid' related kernel arguments
SplitKernelArg () { eval $1='$( IFS=,; echo $2)' }

# Define 'SplitConfArgs' to help extract system configuration arguments
SplitConfArgs () {
    RaidBootType=$1
    RaidBootDevice=$2
    RaidConfigPath=$3
}
#####
##### MAIN linuxrc #####
#####
# mount the proc file system
/bin/mount /proc

# Get the boot partition and configuration location from command line
CMDLINE=`/bin/cat /proc/cmdline`
for Parameter in $CMDLINE; do
    Parameter=$( IFS='='; echo ${Parameter} )
    case $Parameter in
        Raid*) SplitKernelArg $Parameter;;
    esac
done

# Everything is fine, let the kernel mount /dev/md0
# tell the kernel to switch to /dev/md0 as the /root device
# The 0x900 value is the device number calculated by:
# 256*major_device_number + minor_device number
echo "/dev/md0 mounted on root"
echo 0x900>/proc/sys/kernel/real-root-dev
# umount /proc to deallocate initrd device ram space
/bin/umount /proc
exit
#----- end linuxrc -----
```

Add 'linuxrc' to initrd boot device

```
cd /root/raidboot
chmod 777 linuxrc
cp -p linuxrc mnt
```

## 4.12 Modifying the rc-scripts for SHUTDOWN

To complete the installation, modify the rc scripts to save the md status to the real root device when shutdown occurs.

```
In slackware this is rc.0 -> rc.6
In debian 'bo' this is in both 'halt' and 'reboot'
```

If you implement this in another distribution, please e-mail the instructions and sample files so they can be included here.

I have modified Bohumil Chalupa's raid stop work-around slightly. His original solution is presented in [Appendix A](#).

Since there are no linux partitions left on the production system except **md0**, the boot partitions are used to store the **raidOK readonly** status. I chose to write a file to each of the duplicate boot partitions containing the status of the md array at shutdown and signifying that the md device has been remounted RO. This allows the system to be fail safe when any of the hard drives die.

## Root RAID HOWTO cookbook

The shutdown script is modified to call [rc.raidown](#) which saves the necessary information to successfully reboot and mount the raid device. Examples of shutdown scripts for various linux distributions are shown in [Appendix B](#).

To capture the raid array shutdown status insert a call to [rc.raidown](#) after any **case** statements (if present) but before the actual shutdown (kills, status saves, etc...) begins and before the file systems are dismounted.

```
##### Save raid boot and status info #####
#
  if [ -x /etc/rc.d/rc.raidown ]; then
    /etc/rc.d/rc.raidown
  fi
##### end raid boot #####
```

After all the file systems are dismounted (the root file system 'will not' dismount) but before any powerfail status check add:

```
##### for raid arrays #####
# Stop all known raid arrays (except root which won't stop)
  if [ -x /sbin/mdstop ]; then
    echo "Stopping raid"
    /sbin/mdstop -a
  fi
#####
```

This will cleanly stop all raid devices except root. Root status is passed to the next boot in **raidstat.ro**.

Copy the rc file to your new raid array, the rescue file system that is still mounted on **/root/raidboot/mnt** and the development system if it is on the same machine.

Modify rescue **etc/fstab** as needed and make sure rescue **mdtab** is correct.

Now copy the rescue disk to your dos partition and everything should be ready to boot the raid device as root.

```
umount mnt
losetup -d /dev/loop0
gzip -9 rescue
```

Copy rescue.gz to your boot partitions.

All that remains is to creat the configuration file **raidboot.conf** and test the new file system by rebooting.

## 4.13 Configuring RAIDBOOT - raidboot.conf

The comments following the example configuration file explain each of the three lines. This example file is for a 4 drive raid5 scsii array with duplicate boot partitions on drives sda1 and sdb1. Put the paramaters descriptive of your file systems here instead.

```
/dev/sda1 /dev/sdb1
linux
raid5.conf
# comments may only be placed 'after' the three
# configuration lines.
#
```

```
# This is 'raidboot.conf'
#
# line one, the partition(s) containing the 'initrd' raid-rescue system
#     It is not necessary to boot from these partitions, however,
#     since the rescue system will not fit on floppy, it is necessary
#     to know which partitions are to be used to load the rescue system
#
# line two, the path to the raidboot config information
#     Where the shutdown status, etc... is located at boot time
#     It does NOT include the mount point information, only 'path'
#     /mntpoint/'path'
#
# line -3-, name of the raid configuration file
#     Current raid configuration file i.e. raid1.conf, raid5.conf
```

### 4.14 Kernel 'loadlin and lilo' variables for RESCUE and RAID

There are two kernel variables for the RESCUE and RAID system, only the first need be specified.

- **Raid\_Conf=msdos,/dev/sda1,raidboot**

This variable points to raid boot device and configuration file. For floppy rescue boot, you may want to specify this on the kernel command line or in the loadlin or lilo boot file

format: 'filesystem-type,device,path-to-config-from-mountpoint'

- **Raid\_ALT=-r,-p5,/dev/md0,/dev/sda3 /dev/sdb3 /dev/sdc3 /dev/sdd3**

Alternate mdadd parameters necessary when booting with non-redundant raid array. These are the comma separated command line parameters for **mdadd**. Unless they are needed to start a failed/non-redundant array, COMMENT OUT OR SPECIFY WITH A 'NULL'.

i.e. **Raid\_ALT=**

Either of these parameters may be specified in the lilo or loadlin boot parameter file or on the loadlin kernel command line. Care must be taken that the maximum line length is not exceeded, however, if the command line is used (128 characters).

When booting with **lilo**, the parameters are included in the lilo config file in the form:

```
append="Raid_Conf=msdos,/dev/sda1,raidboot"
append="Raid_ALT=-r,-p5,/dev/md0,/dev/sda3 /dev/sdb3 /dev/sdc3 /dev/sdd3"
```

See **man lilo.conf** for more detailed information.

Since I have some hardware that requires DOS configuration utilities, I have a small dos partition on the system. Therefore, I used loadlin to boot the raid5 system from the dos partition with a mirror (copy) on the companion disk. An identical method is used for the raid1 system. The example below uses loadlin, but the procedure is very similar for lilo.

My dos root system contains a small editor among the utilities so I can modify the boot parameters of loadlin if necessary, allowing me to reboot the linux system on my swap disk while testing.

## Root RAID HOWTO cookbook

The dos system contains this tree for linux"

```
c:\raidboot.bat
c:\raidboot\loadlin.exe
c:\raidboot\zimage
c:\raidboot\rescue.gz
c:\raidboot\raidboot.cfg
c:\raidboot\raidboot.etc
c:\raidboot\raidgood.ref
c:\raidboot\raidstat.ro (only at shutdown)
```

linux.bat contains:

```
----- linux.bat -----
echo "Start the LOADLIN process:"
c:\raidboot\loadlin @c:\raidboot\boot.par
----- end linux.bat -----
```

boot.par contains:

```
# loadlin boot parameter file
#
# version 1.02 3-6-98

# linux kernel image
c:\linux\zimage

# target root device
root=/dev/md0
#root=/dev/ram0
#root=/dev/sdc5

# mount root device as 'ro'
ro

# size of ram disk
ramdisk_size=16384

# initrd file name
initrd=c:\raidboot\rescue.gz
#noinitrd

# memory ends here
mem=131072k

# points to raid boot device, configuration file
# for floppy rescue boot, you may want to specify
# this on the command line instead of here
# format 'filesystem-type,device,path-to-config-frm_mntpnt'
Raid_Conf=msdos,/dev/sda1,raidboot

# Alternate mdadd parameters
# necessary when boot with non-redundant raid
# otherwise, COMMENT OUT OR SPECIFY 'NULL'
#Raid_ALT=-r,-p5,/dev/md0,/dev/sda3 /dev/sdb3 /dev/sdc3 /dev/sdd3

# ethernet devices
ether=10,0x300,eth0
```

\*\*\*\*\* >> NOTE!! the only difference between forcing the rescue system to

## Root RAID HOWTO cookbook

run and the raid device mounting, is the loadlin parameter

```
root=/dev/ram0      for the rescue system
root=/dev/md0       for RAID
```

With root=/dev/ram0 the RAID device will not mount  
and the rescue system will run unconditionally.

If the RAID array fails, the rescue system is left mounted and running.

## 5. Configuring the Production RAID system.

### 5.1 System specs. Two systems with identical motherboards were configured.

Motherboard:	Iwill P55TU	Raid-1	Raid-5
Processor:	Intel P200	dual ide	adaptec scsi
Disks:		2ea 7 gig Maxtors	4 ea Segate 4.2 gig wide scsii

The disk drives are designated by linux as 'sda' through 'sdd' on the raid5 system and 'hda' and 'hdc' on the raid1 system.

### 5.2 Partitioning the hard drives.

Since testing a large root mountable RAID array is difficult because of the ckraid re-boot problem, I re-partitioned my swap space to include a smaller RAID partition for testing purposes, sda6,sdb6,sdc6,sdd6, and a small root and /usr/src partition pair for developing and testing the raid kernel and tools. You may find this helpful.

```
<bf/DEVELOPMENT SYSTEM - RAID5/
Device      System      Size      Purpose
/dev/sda1   dos boot     16 meg    boot partition
* /dev/sda2   extended    130 meg   (see below)
/dev/sda3   linux native 4 gig     primary raid5-1
-----sda2-----
* /dev/sda5   linux swap   113 meg   SWAP space
* /dev/sda6   linux native 16 meg    test raid5-1
=====
/dev/sdb1   dos boot     16 meg    boot partition duplicate
* /dev/sdb2   extended    130 meg   (see below)
/dev/sdb3   linux native 4 gig     primary raid5-2
-----sdb2-----
* /dev/sdb5   linux swap   113 meg   SWAP space
* /dev/sdb6   linux native 16 meg    test raid5-2
=====
* /dev/sdc2   extended    146 meg   (see below)
/dev/sdc3   linux native 4 gig     primary raid5-3
-----sdc2-----
* /dev/sdc5   linux swap   130 meg   development root partition
* /dev/sdc6   linux native 16 meg    test raid5-3
=====
* /dev/sdd2   extended    146 meg   (see below)
```

## Root RAID HOWTO cookbook

```

/dev/sdd3      linux native      4 gig   primary raid5-4
-----sdd2-----
* /dev/sdd5      linux swap        130 meg development /usr/src
* /dev/sdd6      linux native      16 meg   test raid5-4

<bf/DEVELOPMENT SYSTEM - RAID1/
Device          System          Size      Purpose

/dev/hda1       dos              16meg     boot partition
* /dev/hda2       extended         126m     (see below)
/dev/hda3       linux            126m     development root partition
/dev/hda4       linux            6+gig     raid1-1
-----hda2-----
* /dev/hda5       linux            26m      test raid1-1
* /dev/hda6       linux swap       100m

=====

/dev/hdc1       is simply an exact copy of hda1 so the
                partition can be made active if hda fails
* /dev/hdc2       extended         126m     (see below)
/dev/hdc3       linux            126m     development /usr/src
/dev/hdc4       linux            6+gig     raid1-2
-----hdc2-----
* /dev/hdc5       linux            26m      test raid1-2
* /dev/hdc6       linux swap       100m

```

The sdx2 and hdx3 partitions were switched to 'swap' after developing this utility. I could have done it on another machine, however, the libraries and kernels are all about a year or more out of date on my other linux boxes and I preferred to build it on the target machine.

The partitioning scheme was chosen so that in the event that any one of the drives fails catastrophically, the system will continue to run and be bootable with minimum effort and NO data loss.

- If any single hard drive fails, the boot will abort, and the rescue system will run. Examination of the screen message or /dosx/raidboot/raidstat.ro will tell the operator the status of the failed array.
- If sda1 (raid5) or hda1 (raid1) fails, the dos backup boot partition must be made 'active' and the bios must recognize the new partition as the boot device or it must be physically be moved to the xda position. Alternatively, the system could be booted from a floppy disk using the initrd image on the remaining backup boot drive. The raid system can then be made active again by issuing:

```
"/sbin/mkraid /etc/raid<it/x/.conf -f --only-superblock"
```

to rebuild the remaining superblock(s).

- Once this is done, then

```
mdadd -ar
```

- Examine the status of the array to verify that everything is OK then replace the good array reference with the current status until the failed disk can be repaired or replaced.

```
cat /proc/mdstat | grep md0 > /dosx/raidboot/raidgood.ref
```

```
shutdown -r now
```

to do a clean reboot, and the system is up again.

## 6. Building the RAID file system.

This description is for my RAID systems described in the system specs. Your system may have a different RAID architecture, so modify as appropriate. Please read the man pages and QuickStart.RAID that come with the raidtools-0.42

### 6.1 /etc/raid5.conf

```
# raid-5 configuration
raiddev                /dev/md0
raid-level              5
nr-raid-disks          4

raid-disk              1
```

## 6.3 Step by Step procedures for building production RAID file system.

For my RAID5 system I did a complete install of:

```
Slackware-3.4          any current distribution should work OK
linuxthreads-0.71
raidtools-0.42
linux-2.0.33 with raid145 patch and Gadi's patch
```

## Root RAID HOWTO cookbook

Create and format the raid device.

```
mkraid /etc/raid5.conf
mdcreate raid5 /dev/md0 /dev/sda3 /dev/sdb3 /dev/sdc3 /dev/sdd3
mdadd -ar
mke2fs /dev/md0
mkdir /md
mount -t ext2 /dev/md0 /md
```

Create the reference files that reboot will use, this may be different on your system.

```
cat /proc/mdstat | grep md0 > /dosa/raidboot/raidgood.ref
cat /proc/mdstat | grep md0 > /dosb/raidboot/raidgood.ref
```

Use Slackware-3.4 or another distribution to build your OS

```
setup
```

Specify '/md' as the target, and the source whatever you normally use. Select and install the disksets of interest except for the kernel. Configure the system, but skip the section on lilo and kernel booting. Exit setup.

Install 'pthreads'

```
cd /usr/src/linuxthreads-0.71
```

edit the Makefile and specify

```
BUILDIR=/md

make
make install
```

Install 'raidtools'

```
cd /usr/src/raidtools-0.42
configure --sbindir=/md/sbin --prefix=/md/usr
```

fix the raidtools make install error

```
cd /md/sbin
rm mdrun
rm mdstop
ln -s mdadd mdrun
ln -s mdadd mdstop
```

Create /dev/mdx

```
cp -a /dev/md* /md/dev
```

Add the system configuration from the current system (ignore errors).

```
cp -dp /etc/* mnt/etc
cp -dp /etc/rc.d/* mnt/etc/rc.d          (include the new rc.6)
mkdir mnt/lib/modules
cp -a /lib/modules/2.x.x mnt/lib/modules <--- your current 2.x.x
```

## Root RAID HOWTO cookbook

Edit the following files to correct them for your file system

```
cd /md

Non-network
  etc/fstab          correct for real root and raid devices.
  etc/mdtab          should work OK

Network
  etc/hosts
  etc/resolv.conf
  etc/hosts.equiv     and related files
  etc/rc.d/rc.inet1   correct ip#, mask, gateway, etc...
  etc/rc.d/rc.S       remove entire section on file system status
                      from:
                        # Test to see if the root partition is read-only
to but not including:
                        # remove /etc/mtab* so that mount will .....
                        This avoids the annoying warning that
                        the ramdisk is mounted rw.
  etc/rc.d/rc.xxxxx   others as required
  root/.rhosts        if present
  home/xxxx/xxxx      others as required

WARNING:    The above procedure moves your password and shadow
            files onto the new file system!!!!

WARNING:    You may not wish to do this for security reasons.
```

Create any directories for mounting /dev/disk... as may be required that are unique to your system. Mine need:

```
cd /md          <--- new file system root
mkdir dosa      dos partition mount point
mkdir dosb      dos mirror mount point
```

The new file system is complete. Make sure and save the md reference status to the 'real' root device and you are ready to boot.

mount the dos partitions on dosa and dosb

```
cat /proc/mdstat | grep md0 > /dosa/raidboot/raidgood.ref
cat /proc/mdstat | grep md0 > /dosb/raidboot/raidgood.ref

mdstop /dev/md0
```

## 7. One last thought.

Remember that an expert is someone who knows at least 1% more than you do about a subject. Bear this in mind when you e-mail me for help. I'll try, but I've only done this once for raid1 and once for raid5!

Michael Robinton [Michael@bzs.org](mailto:Michael@bzs.org)

## 8. Appendix A. - Bohumil Chalupa's md0 shutdown

Bohumil Chalupa's post to the linux raid list on the work around for the raid1 + 5 mdstop problem. His solution does not address the possibility of the raid device being corrupt at shutdown. So I have added a

## Root RAID HOWTO cookbook

simple status comparison to a good reference status at boot. This allows the operator to intervene if something is wrong with a disk in the array. The description of this is in the main body of this document.

```
> From: Bohumil Chalupa <bochal@apollo.karlov.mff.cuni.cz>
>
> I can now boot initrd and use linuxrc to start the RAID1 array,
> then successfully switch root to /dev/md0.
>
> I don't know, however, any way how to cleanly _stop_ the array.
```

Well. I have to answer myself :-)

```
> Date: Mon, 29 Dec 1997 02:21:38 -0600 (CST)
> From: Edward Welbon <welbon@bga.com>
> Subject: Re: dismounting root raid device
>
> For md devices other than raid0, there is probably state that needs to
> be saved that is only known once all writes have completed. Such state
> of course can't be saved to root once it is mounted readonly. In that
> case, you would have to be able to mount a writeable filesystem "X"
> on the readonly root and be able to write to "X" (I recall doing this
> during "rescue" operations, but not as an automated procedure).
>
> The filesystem "X" would presumably be a boot device from which the raid
> (during linuxrc exection via initrd) would pickup it's initial state from.
> Fortunately raid0 isn't required to write out any state (though it would
> be pleasant to be able to write the check sums to mdtab after an mdstop).
> Eventually, I will fiddle with this but it doesn't seem difficult though
> the "devil" is always in the "details".
```

Yes, that's it.

I had this idea in mind for some time already, but had no time to try it.  
Yesterday I did, and it works.

With my RAID1 (mirror), I don't save any checksums or raid superblock data.  
I only save an information on the "real" boot partition, that the root md  
volume was remounted readonly during shutdown. Then, during boot, the  
linuxrc script runs mkraid --only-superblock when it finds this  
information; otherwise, it runs ckraid.  
This means, that the raid superblock information is not updated during  
shutdown; it's updated at the boot time.  
It is not very clean, I'm afraid, :-( but it works.

I'm using Slackware and initrd.md by Edward Welbon to boot the root raid  
device.

As far as I remember now, the only modified files are  
mkdisk and linuxrc, and /etc/rc.d/rc.6 shutdown script.  
And lilo.conf, of course.

I'm appending the important parts.

Bohumil Chalupa

```
----- my.linuxrc follows -----
#!/bin/sh
# we need /proc
/bin/mount /proc
# start up the md0 device. let the /etc/rc.d scripts get the rest of them
# we should do as little as possible here
# -----
# root raid1 shutdown test & recreation
# /start must be created on the rd image in my.mkdisk
```

## Root RAID HOWTO cookbook

```

# 11. Appendix D. - obsolete linuxrc and shutdown scripts

## 11.1 Obsolete working - linuxrc

This linuxrc file works fine with the shutdown procedure in the next subsection.

```

----- linuxrc -----
#!/bin/sh
# ver 1.07 2-12-98
# linuxrc - for raid1 using small dos partition and loadlin
#

# mount the proc file system
/bin/mount /proc

# This may vary for your system.
# Mount the dos partitions, try both
# in case one disk is dead
/bin/mount /dosa
/bin/mount /dosc

# Set a flag in case the raid status file is not found
# then check both drives for the status file
RAIDOWN="raidstat.ro not found"
/bin/echo "Reading md0 shutdown status."
if [ -f /dosa/raidboot/raidstat.ro ]; then
    RAIDOWN="/bin/cat /dosa/raidboot/raidstat.ro"
    RAIDREF="/bin/cat /dosc/raidboot/raidgood.ref"
else
    if [ -f /dosc/raidboot/raidstat.ro ]; then
        RAIDOWN="/bin/cat /dosc/raidboot/raidstat.ro"
        RAIDREF="/bin/cat /dosc/raidboot/raidgood.ref"
    fi
fi

# Test for a clean shutdown with all disks operational
if [ "${RAIDOWN} != ${RAIDREF}" ]; then
    echo "ERROR ${RAIDOWN}"
    # Use the next 2 lines to BAIL OUT and leave rescue running
    /bin/echo 0x100>/proc/sys/kernel/real-root-dev
    exit # leaving the error files in dosa/raidboot,etc...
fi

# The raid array is clean, proceed by removing
# status file and writing a clean superblock
/bin/rm /dosa/raidboot/raidstat.ro
/bin/rm /dosc/raidboot/raidstat.ro
/sbin/mkraid /etc/raid1.conf -f --only-superblock

/bin/umount /dosa
/bin/umount /dosc

# Mount raid array

```

## Root RAID HOWTO cookbook

```
echo "Mounting md0, root filesystem"
/sbin/mdadd -ar

# If there are errors - BAIL OUT and leave rescue running
if [ $? -ne 0 ]; then
    echo "RAID device has errors"
# Use the next 3 lines to BAIL OUT
    /bin/rm /etc/mtab          # remove bad mtab
    /bin/echo 0x100>/proc/sys/kernel/real-root-dev
    exit
fi

# else tell the kernel to switch to /dev/md0 as the /root device
# The 0x900 value the device number calculated by:
# 256*major_device_number + minor_device number
/bin/echo 0x900>/proc/sys/kernel/real-root-dev

# umount /proc to deallocate initrd device ram space
/bin/umount /proc
/bin/echo "/dev/md0 mounted as root"
exit
#----- end linuxrc -----
```

## 11.2 Obsolete working - shutdown scripts

This shutdown procedure works fine with the preceeding **linuxrc**

To capture the raid array shutdown status, just before the file systems are dismounted insert:

```
RAIDSTATUS=`/bin/cat /proc/mdstat | /usr/bin/grep md0`
```

After all the file systems are dismounted (the root file system 'will not' dismount) add:

```
# root device remains mounted RO
# mount dos file systems RW
mount -n -o remount,ro /
echo "Writing RAID read-only boot FLAG(s)."
mount -n /dosa
mount -n /dosc
# create raid mounted RO flag in duplicate
# containing the shutdown status of the raid array
echo ${RAIDSTATUS} > /dosa/raidboot/raidstat.ro
echo ${RAIDSTATUS} > /dosc/raidboot/raidstat.ro

umount -n /dosa
umount -n /dosc

# Stop all the raid arrays (except root)
echo "Stopping raid"
mdstop -a
```

This will cleanly stop all raid devices except root. Root status is passed to the next boot in **raidstat.ro**.

The complete shutdown script from my old raid1 Slackware system follows, I have switched raid1 to the new procedure with the /etc/raidboot.conf file.

```
#!/bin/sh
#
```

```

## 14. Appendix G. - linuxrc theory of operation

This is the complex form of the linuxrc file for root mounted raid. It must be processed with 'bash' or another shell that recognizes shell functions.

The advantage is that it is generic and is not dependent on startup files and parameters located in the **initrd** image.

A **Raid\_Conf** parameter passed to **linuxrc** by the kernel at boot from lilo or loadlin contains a pointer to the boot devices and location the of initial 2 raidboot files needed by **linuxrc** (*raidboot.etc and raidboot.cfg placed by the shutdown script*).

**raidboot.etc** containing the 'tar'ed files:

```
raid*  
mdtab*  
fstab  
lilo.conf          ( if applicable )
```

## Root RAID HOWTO cookbook

from the primary system that are transferred to the `initrd /etc` directory at startup. With care, this file may be edited if necessary when your system 'really' crashes.

**raidboot.cfg** contains the name of the boot partition in use and applicable backup(s) as well as the path to the rest of the raid start up file used by **linuxrc**. This file is normally created by the shutdown file and may be created manually if necessary.

**raidboot.cfg** is of the form, 3 lines - no comments

```
/dev/bootdev1 /dev/bootdev2 [/dev/bootdev3 ... and so on]
raid-status/path
name_of_raidX.conf_file
```

the **raid-status/path** does not include the name of the mountpoint

the **raidX.conf** filename is that one found in `/etc` and normally used for **ckraid** and **mkraid**.

The following additional files reside on the permanent raid boot partitions. This is usually the same as above, but in emergency situations may be loaded from anywhere they are available, such as a floppy boot disk.

- **raidgood.ref** created by the command `cat /proc/mdstat | grep md0 > /{raid_status_path}/raidgood.ref`

See the [shutdown scripts](#) for saving this file and the next

- **raidstat.ro** created at each shutdown by the shutdown rc file, saving the exit status of the raid array.

## 15. Appendix H. Setting up ROOT RAID on RedHat

From the [linux-raid@vger.rutgers.edu](mailto:linux-raid@vger.rutgers.edu) mail list.

```
!   Has anyone figured out how to do root-mounted RAID (as per
!   the Root-RAID HOWTO) using RedHat? The problem is that there
!   is no equivalent of Slackware's setup to install the root
!   filesystem to the RAID device. All RedHat installs have to
!   run from the install floppy, which makes it almost
!   impossible to get at the md devices and utilities during the
!   install.
!
!   I think it's much easier to go out of the distribution and do it by
!   hand!!
```

Assuming you have enough RAM (or a spare hard disk), install a minimal system onto what will be your swap space (or onto your spare hard disk) and/or `/boot`. Now do your `mkraid`, your `mke2fs`, `mdrun`, and `mount`. Next, do:

```
tar clf - / | tar xpfC - /mnt/raidwasmountedhere
```

(you may want a "v" in the second tar's flags)  
Once this is done, you can set up `lilo` (or whatever) so that the new raid partition is root. Then go in with `RPM` and/or `glint` (I hate `glint`'s behavior in the face of failed dependencies, which was fixed but they broke it again for RH5.0 plus you can go back and forth forever between an old and a new version of a package without realizing the other version is installed) and install what you really wanted.

## Root RAID HOWTO cookbook

All this assuming you couldn't sneak in at some point in the install and do your mkraid then at the VC with the shell prompt...

```
!   I'm building a server at the moment and I think it would be tidier
!   and less likely to cause problems in the future if I start with
!   glibc2, rather than move to it later.
!
!   Me too.
!
!   The reason I'd like to be able to use RedHat is that they
!   are the only major distribution that I know of with a
!   glibc2-based release.
!
!   Debian works fine with me. There isn't a CD yet, but you can grab the
!   distribution by ftp.
```

I avoided root-raid like the plague, largely because initrd is an extra, very fragile step (having to rdev, and having lilo depend on the bios' ID number to find the kernel's partition, are bad enough!). However, Red Hat does have a nice mkinitrd script, needed since they left all their SCSI drivers modular. Hack that to include your raid utils, make sure your mdadd -ar is in the right spot in /etc/rc.d/rc.sysinit (before any fscking) and make sure mdstop -a is in /etc/rc.d/init.d/halt after the RO-remount of /, and go for it!
